Rice Example: Multiple Regression and the car() package

Multiple regression extends the simple linear regression model to include multiple predictor variables. In this example, we consider the yield (response) versus height and tillers (predictors) for n = 8 varieties of rice.

We go beyond the basic model fitting using lm() to illustrate several topics:

- 1. Predicted values, confidence intervals and prediction intervals using the predict() function.
- 2. Additional hypothesis tests using lht() from the car package. Comparing a reduced versus full model using anova().
- 3. When there are two or more predictors, anova() is different from Anova() from the car package. We are generally interested in the Anova results! Anova() gives the unique (or marginal) ANOVA table (which does not depend on the order the predictors are listed). anova() gives the sequential ANOVA table (which depends on the order the predictors are listed).

```
library(scatterplot3d)
library(car)
Rice <- read.csv("~/Dropbox/STAT512/Lectures/MultReg1/MR1_Rice.csv")</pre>
Rice
     yield
              ht tillers
## 1 5.755 110.5

```

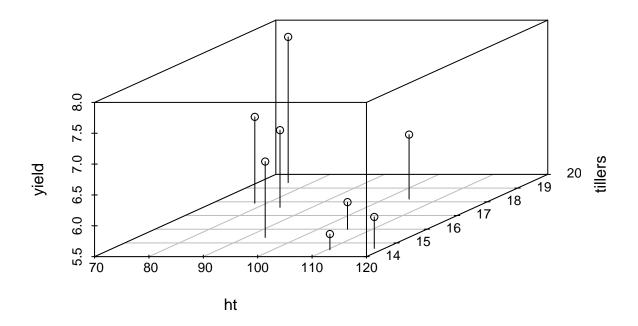

Pairwise correlations and plots

The cor function is handy for computing pairwise correlations. But in order to get a formal test of correlation, we need to use cor.test().

```
cor(Rice)
                            \psi_{	ext{ht}}
##
                vield

anova vs Anova

When there is just a single predictor, there is no difference between anova() and Anova(). But when there are now two predictors, there is a difference between anova() and Anova() from the car package. In general, we will be using Anova(). anova() can be used to compare a reduced vs full model.
