Design Matrix Example (For Illustration)

We look at the design matrix in the context of simple linear regression. We start with the standard analysis in R and get the estimated coefficients.

```
Corn <- read.csv("~/Dropbox/STAT512/Lectures/R_Stuff & Intro/Corn.csv")</pre>
##
      Yield X
## 1
         12 2
## 2
         13 2
## 3
         13 3
## 4
         14 3
## 5
         15 4
         15 4
## 7
         14 5
## 8
         16 5
## 9
         17 6
## 10
         18 6
Fit <- lm(Yield ~ X, data = Corn)
summary(Fit)
                               Cortilizer
##
## Call:
## lm(formula = Yield ~ X, data = Corn)
## Residuals:
       Min
                10 Median
                                 30
                                        Max
## -1.8500 -0.3000 0.2250 0.4125
                                    1.0000
##
                                                              , Ho: p, = D
##
  Coefficients:
##
               Estimate Std. Error t value Pr(>|t|)
                                      12.67 1.42e-06 ***
## (Intercept)
                10.1000
                             0.7973
                                       6.12 0.000283 ***
## X
                 1.1500
                             0.1879
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
## Residual standard error: 0.8404 on 8 degrees of freedom
## Multiple R-squared: 0.824, Adjusted R-squared: 0.802
## F-statistic: 37.45 on 1 and 8 DF, p-value: 0.0002832
Now we look at the design matrix and estimate the coefficients "by hand". solve() takes the inverse of a
matrix. t() transposes a matrix. %*% is used for matrix multiplication.
model.matrix(Fit)
##
      (Intercept) X
                1 2
## 1
                1 2
## 2
                1 3
## 3
                1 3
## 5
                1 4
## 6
                1 4
## 7
                1 5
```
